Experiment No. 7: Zoho Creator API Integration

1. AIM

To study API integration in Zoho Creator and understand how REST APIs enable communication between applications.

2. THEORY

An **Application Programming Interface (API)** allows two software applications to communicate and exchange data. Zoho Creator supports API integration to retrieve, create, update, and delete records.

REST API uses HTTP methods to perform operations:

- **GET:** Retrieve data.
- **POST:** Create records.
- **PUT/PATCH:** Update records.
- **DELETE:** Remove records.

APIs use authentication, endpoints, request headers, and responses. JSON is commonly used for data exchange, while OAuth 2.0 provides secure authorization.

3. PROCEDURE

1. Log in to Zoho Creator and open the application.
2. Select the form or report for integration.
3. Identify the required API endpoint and HTTP method.
4. Configure OAuth authentication and permissions.
5. Send an API request using an authorized API testing tool.
6. Examine the response and verify the returned data.
7. Check errors and correct the configuration if necessary.

Example request:

```
None
GET
https://www.zohoapis.com/creator/v2.1/data/OWNER/APP/report/REPORT
```

The endpoint placeholders must be replaced with the actual account and application details, and the request must include valid authentication.

4. APPLICATION

In the Vehicle Service Management application, APIs can retrieve vehicle service records and display them in an external dashboard.

Component	Description
Platform	Zoho Creator
Method	GET
Authentication	OAuth 2.0
Response Format	JSON
Purpose	Retrieve service request records

5. RESULT

Zoho Creator API integration was studied successfully. The experiment demonstrated how REST APIs, HTTP methods, OAuth authentication, and JSON facilitate secure data exchange between Zoho Creator and external applications.
